

# **Chapter 9: Virtual Memory**

## **Chapter 9: Virtual Memory**

- 9.1 Background
- 9.2 Demand Paging
- 9.3 Copy-on-Write
- 9.4 Page Replacement
- 9.5 Allocation of Frames
- 9.6 Thrashing
- 9.7 Memory-Mapped Files
- 9.8 Allocating Kernel Memory
- 9.9 Other Considerations
- 9.10 Operating-System Examples
- 9.11 Summary

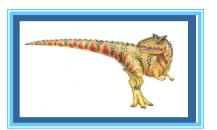

## **Objectives**

- To describe the benefits of a virtual memory system
- To explain the concepts of demand paging, page-replacement algorithms, and allocation of page frames
- To discuss the principle of the working-set model

# 9.1 Background

## **Background**

- Virtual Memory: Only part of a running program needs to be loaded into memory for execution
  - Virtual memory separates user logical memory from physical memory
  - Logical (or virtual) address space can be larger than physical address space
  - Allows physical address space to be shared by several processes
  - Enables quicker process creation

What about fork()?

- Virtual memory can be implemented via:
  - Demand paging (请求调页,按需调页,请求页式管理)
  - Demand segmentation (请求段式管理)

## principle of locality

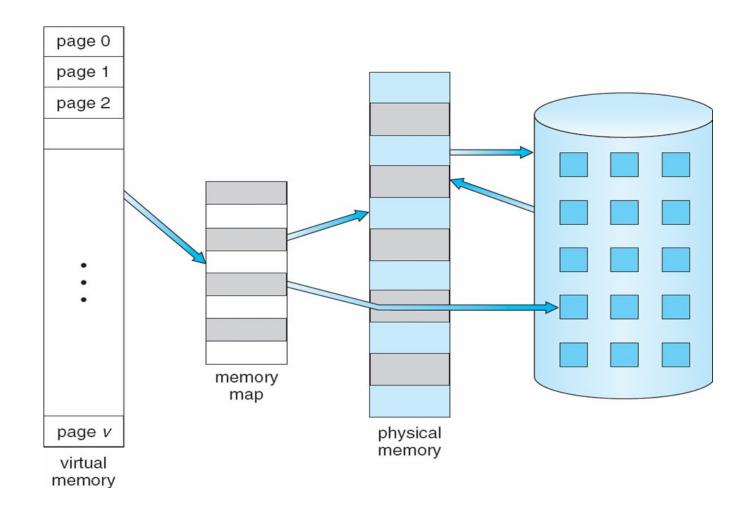

- 局部性原理 (principle of locality): 指程序在执行过程中的一个较短时期,所执行的指令地址和指令的操作数地址,分别局限于一定区域。表现为:
  - 时间局部性:一条指令的一次执行和下次执行,一个数据的一次访问和下次访问都集中在一个较短时期内;
  - 空间局部性:当前指令和邻近的几条指令,当前访问的数据和邻近的数据 都集中在一个较小区域内。

■ 虚拟存储器是具有请求调入功能和置换功能,能仅把进程的一部分装入内存便可运行进程的存储管理系统,它能从逻辑上对内存容量进行扩充的一种虚拟的存储器系统

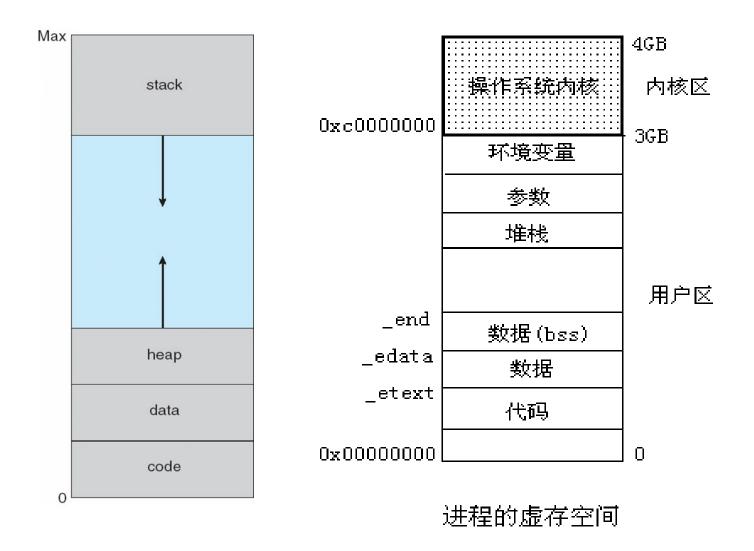

### **Virtual Memory That is Larger Than Physical Memory**

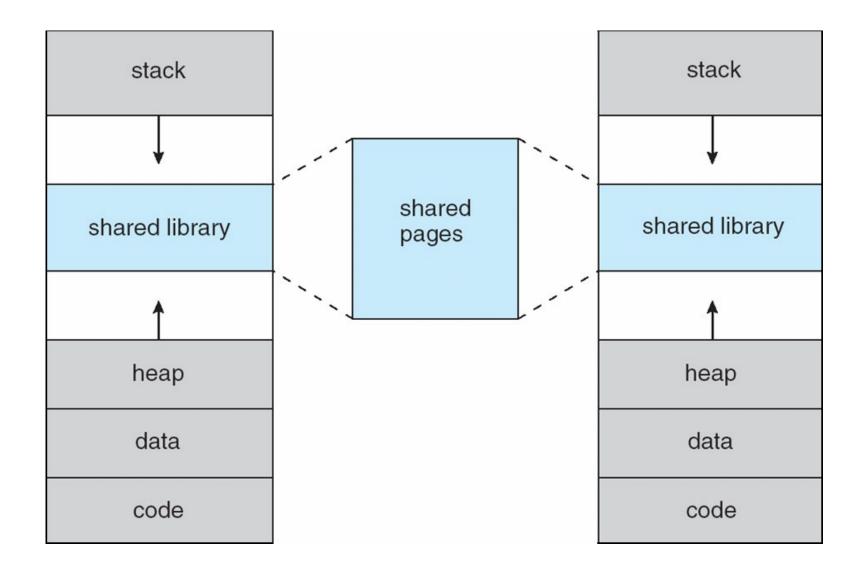

## Virtual-address Space (虚拟地址空间)

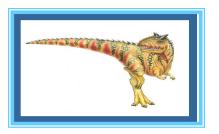

## **Shared Library Using Virtual Memory**

# 9.2 Demand Paging (按需调页、请求调页)

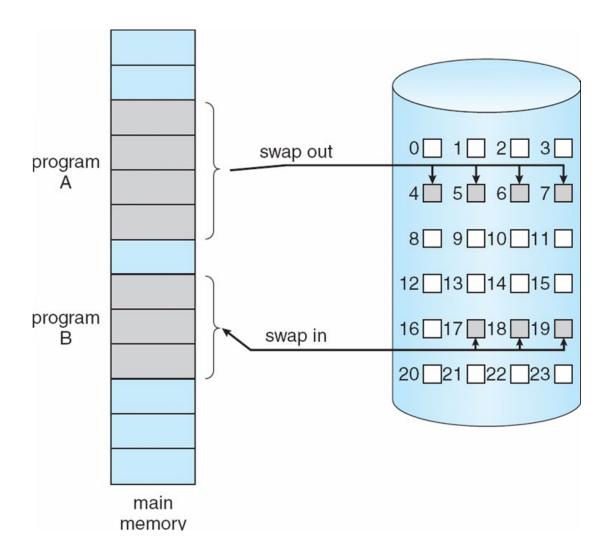

## **Demand Paging**

- Bring a page into memory only when it is needed
  - Less I/O needed
  - Less memory needed
  - Faster response
  - More users
- Page is needed ⇒ reference to it
  - invalid reference ⇒ abort
  - not-in-memory ⇒ bring to memory
- Lazy swapper never swaps a page into memory unless page will be needed
  - Swapper that deals with pages is a pager

#### Transfer of a Paged Memory to Contiguous Disk Space

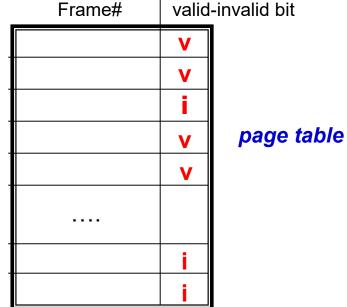

#### **Valid-Invalid Bit**

- With each page table entry a valid–invalid bit is associated (v ⇒ in-memory, i ⇒ not-in-memory)
- Initially valid—invalid bit is set to i on all entries
- Example of a page table snapshot:

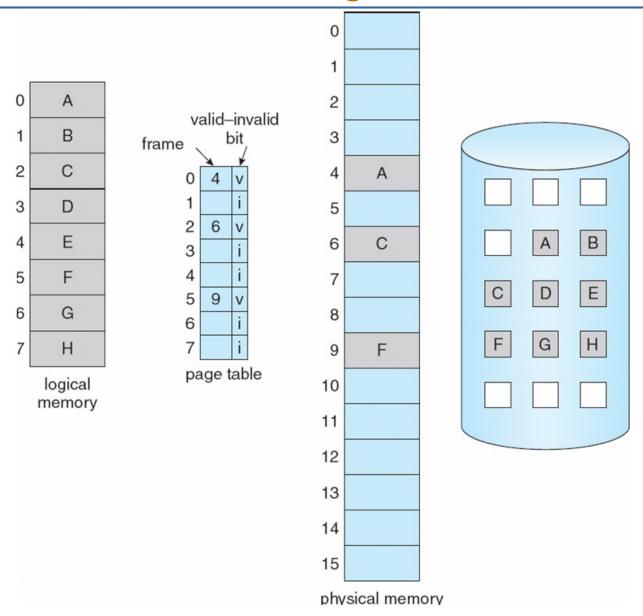

■ During address translation, if valid—invalid bit in page table entry is i ⇒ page fault

#### Page Table When Some Pages Are Not in Main Memory

## 更完整的页表

■ 在请求分页系统中的每个页表项如图所示:

物理块号	状态位P	访问字段A	修改位M	外存地址

- 状态位P(存在位):用于指示该页是否已调入内存,供程序访问时参考。
- 访问字段A: 用于记录本页在一段时间内被访问的次数, 或最近已有多长时间未被访问, 提供给置换算法选择换出页时参考。
- 修改位R/W:表示该页在调入内存后是否被修改过。
- 外存地址: 用于指出该页在外存上的地址, 供调入该页时使用。

## Page Fault (缺页)

If there is a reference to a page, first reference to that page will trap to operating system:

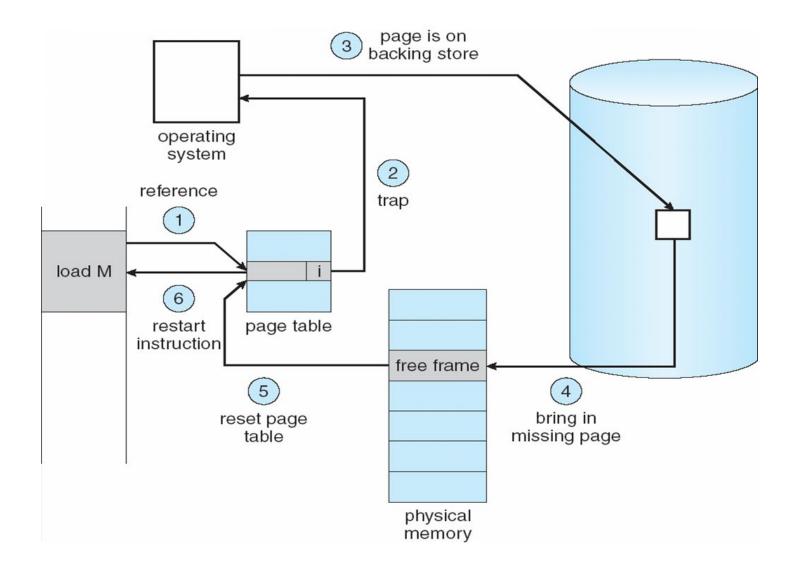

#### page fault

- 1. Operating system looks at another table to decide:
  - Invalid reference ⇒ abort (非法地址访问)
  - Just not in memory
- 2. Get empty frame
- 3. Swap page into frame
- 4. Reset tables
- 5. Set validation bit = v
- 6. Restart the instruction that caused the page fault

## **Steps in Handling a Page Fault**

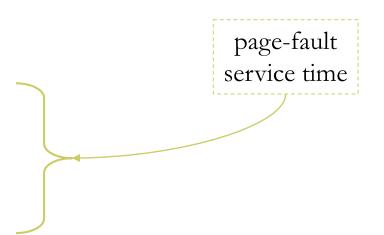

## **Demand Paging Performance**

- The page fault rate p is in the range [0.0, 1.0]:
  - If p is 0.0, no page faults at all
  - If *p* is 1.0, every page is a page faualt
  - Typically p is very low....
- The effective memory-access time is

```
    (1 – p) x physical-memory-access +
    p x (page-fault-overhead +
    swap-page-out +
    swap-page-in +
    restart-overhead )
```

### **Performance of Demand Paging**

- To compute the **EAT**, we must know how much time is needed to service a page fault. A page fault causes the following sequence to occur:
  - Trap to the OS.
  - 2. Save the user registers and process state.
  - 3. Determine that the interrupt was a page fault.
  - 4. Check that the page reference was legal and determine the location of the page on the disk.
  - 5. Issue a read from the disk to a free frame:
    - Wait in a queue for this device until the read request is serviced.
    - Wait for the device seek time and latency time.
    - Begin the transfer of the page to a free frame.

#### **Performance of Demand Paging**

- 6. While waiting, allocate the CPU to some other user (CPU scheduling, optional).
- 7. Interrupt from the disk (I/O completed).
- 8. Save the registers and process state for the other user (if step 6 is executed).
- 9. Determine that the interrupt was from the disk.
- 10. Correct the page table and other tables to show that the desired page is now in memory.
- 11. Wait for the CPU to be allocated to this process again.
- 12. Restore the user registers, process state, and new page table, then resume the interrupt instruction.

### **Performance of Demand Paging**

- Three major components of the page-fault service time
  - Service the page-fault interrupt(缺页中断服务时间)
  - Read in the page(将缺页读入时间)
  - Restart the process(重新启动进程时间)

## **Demand Paging Example**

Memory access time = 200 nanoseconds (ns)

microsecond--us

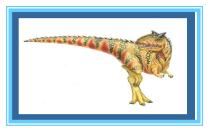

- Average page-fault service time = 8 milliseconds (ms)
- EAT =  $(1 p) \times 200 \text{ ns} + p \times 8 \text{ ms}$ =  $(1 - p \times 200 \text{ ns} + p \times 8,000,000 \text{ ns}$ =  $200 + p \times 7,999,800 \text{ ns}$
- If one access out of 1,000 causes a page fault (p=0.001), then EAT = 8200 ns

This is a slowdown by a factor of 40!!

# 9.3 Process Creation

### **Process Creation**

- Virtual memory allows other benefits during process creation:
  - Copy-on-Write(写时拷贝)

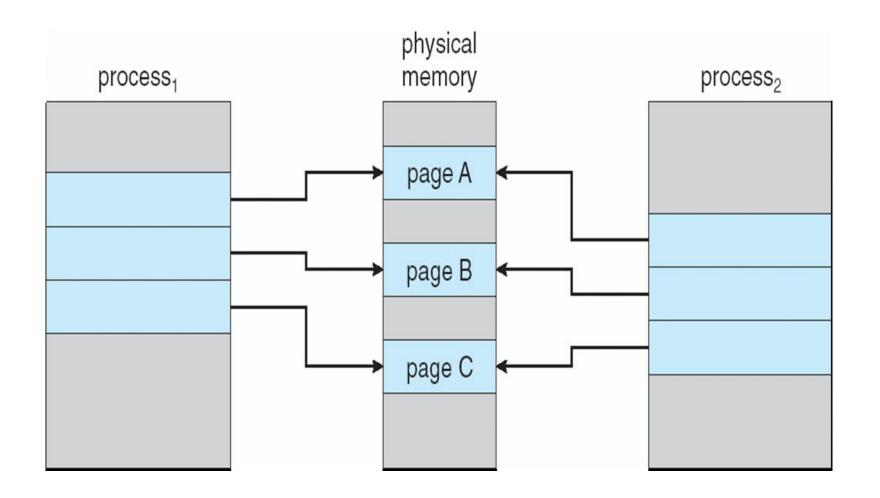

## **Copy-on-Write**

- Copy-on-Write (COW) allows both parent and child processes to initially share the same pages in memory If either process modifies a shared page, only then is the page copied
- COW allows more efficient process creation as only modified pages are copied
- Free pages are allocated from a pool of zeroed-out pages
- Windows Linux Solaris

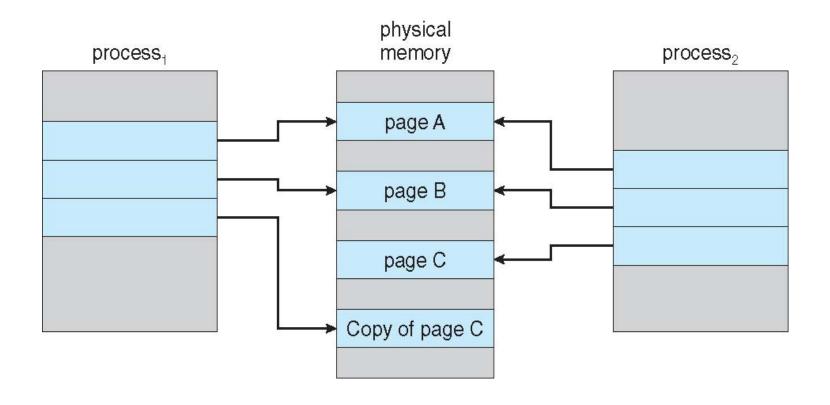

## **Before Process 1 Modifies Page C**

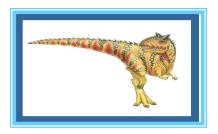

## After Process 1 Modifies Page C

# 9.4 Page Replacement (页面置换)

### Page Replacement 页面置换

#### What happens if there is no free frame?

- Page replacement find some page in memory, but not really in use, swap it out
  - algorithm
  - performance want an algorithm which will result in minimum number of page faults
- Same page may be brought into memory several times

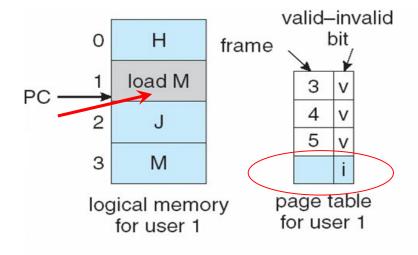

## Page Replacement

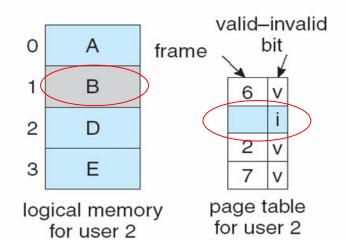

- Prevent over-allocation of memory by modifying page-fault service routine to include page replacement
- Use modify (dirty) bit to reduce overhead of page transfers only modified pages are written to disk
- Page replacement completes separation between logical memory and physical memory – large virtual memory can be provided on a smaller physical memory

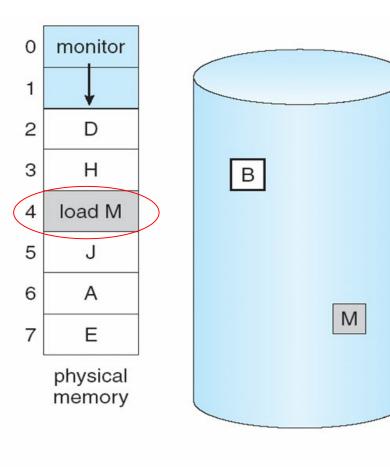

## **Need For Page Replacement**

## **Basic Page Replacement**

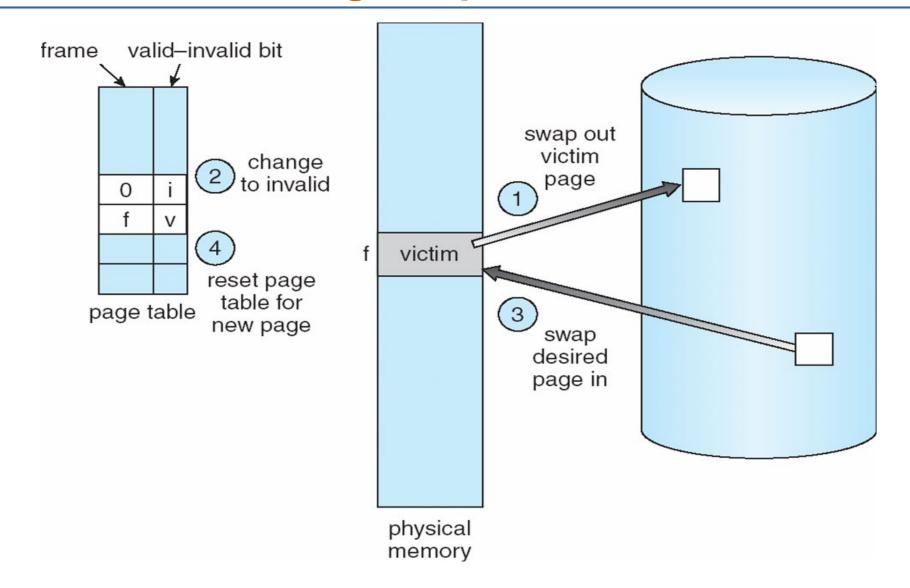

#### ■ 页面置换的过程:

- 1. Find the location of the desired page on disk
- 2. Find a free frame:
  - If there is a free frame, use it
  - If there is no free frame, use a page replacement algorithm to select a victim (海汰) frame
  - Write the victim page to the disk; change the page and frame tables accordingly.
- 3. Bring the desired page into the (newly) free frame; update the page and frame tables
- 4. Restart the process

## Page Replacement

## Page Replacement Algorithms

- Want lowest page-fault rate
- Evaluate algorithm by running it on a particular string of memory references (reference string, 引用串) and computing the number of page faults on that string
- reference string:(100 bytes per page)
  0100, 0432,0101,0612, 0102,0103,0104,0611,0120 → 1,4,1,6,1,6,1

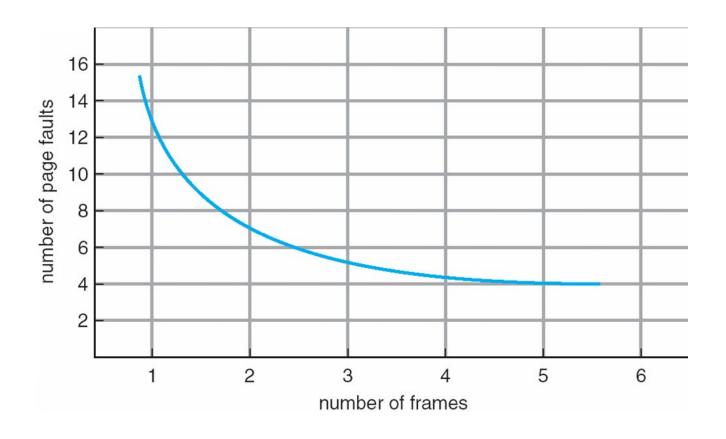

■ In all our examples, the reference string is

```
1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5
7,0,1,2,0,3,0,4,2,3,0,3,2,1,2,0,1,7,0,1.\(\sigma\)
```

#### **Graph of Page Faults Versus The Number of Frames**

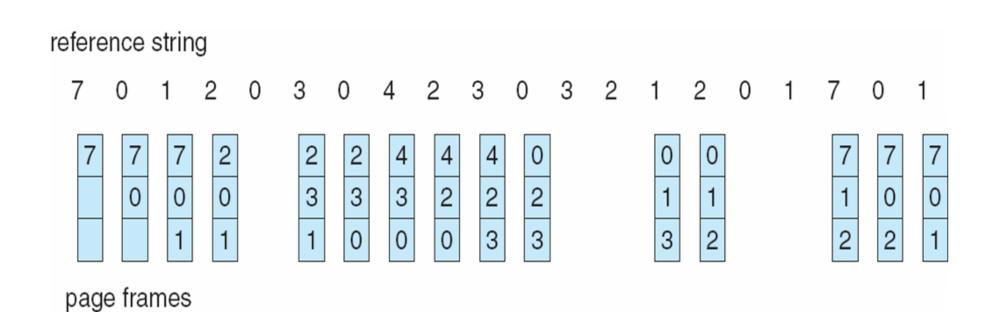

#### Page Replacement Algorithms

- First-In-First-Out Algorithm (FIFO, 先进先出算法)
- Optimal Algorithm (OPT 最佳页面置换算法)
- Least Recently Used (LRU) Algorithm (最近最久使用算法)
- LRU Approximation Algorithms (近似LRU算法):
  - Additional-Reference-Bits Algorithm
  - Second-Chance (clock) Algorithm
  - Enhanced Second-Chance Algorithm
- Counting-Base Page Replacement:
  - Least Frequently Used Algorithm (LFU最不经常使用算法)
  - Most Frequently Used Algorithm (MFU引用最多算法)
- Page Buffering Algorithm(页面缓冲算法)

### FIFO Page Replacement

How many page faults occur?

15 Page faults

### First-In-First-Out (FIFO) Algorithm

- Reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5
- 3 frames (3 pages can be in memory at a time per process)

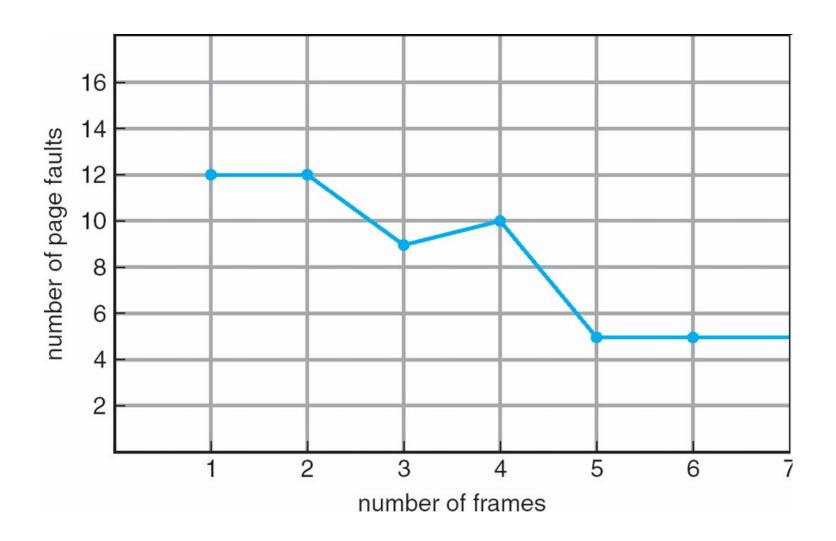

4 frames

■ Belady's Anomaly: more frames ⇒ more page faults

### FIFO Illustrating Belady's Anomaly

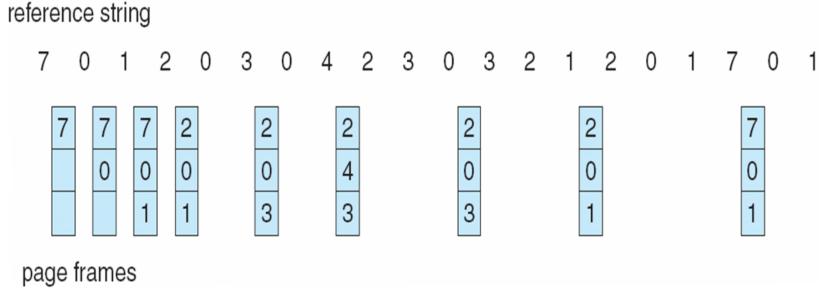

### **Optimal Page Replacement**

- **OPT**(最佳页面置换算法): Replace page that will not be used for longest period of time。选择"未来不再使用的"或"在离当前最远位置上出现的"页被置换。
- How do you know this?
- Used for measuring how well your algorithm performs

9 Page faults

### **Optimal Algorithm**

4 frames example

1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5

6 page faults

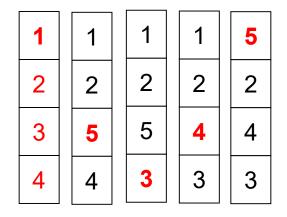

#### Least Recently Used (LRU) (最近最久使用) Algorithm

■ LRU(最近最少使用算法): 选择内存中最久没有引用的页面被置换。这是局部性原理的合理近似,性能接近最佳算法。但由于需要记录页面使用时间,硬件开销太大。

■ Reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5

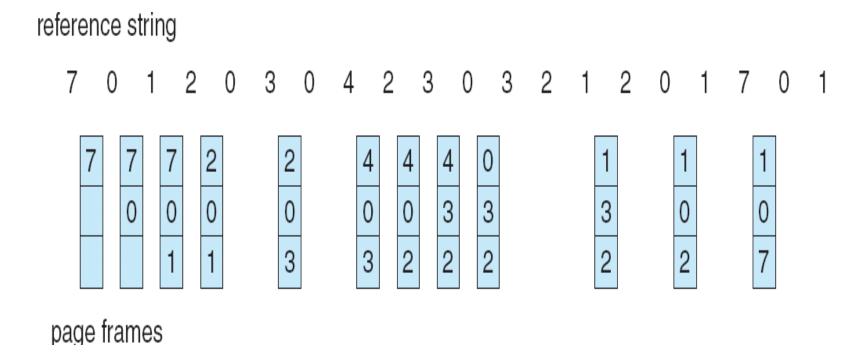

8 Page faults

### LRU Page Replacement

12 Page faults

#### LRU算法,如何获知"多长时间没引用"?

#### Counter implementation

- Every page entry has a counter; every time page is referenced through this entry, copy the clock into the counter
- When a page needs to be changed, look at the counters to determine which are to change
- Stack implementation keep a stack of page numbers in a double link form:
  - Page referenced:
    - move it to the top
    - requires 6 pointers to be changed
  - No search for replacement

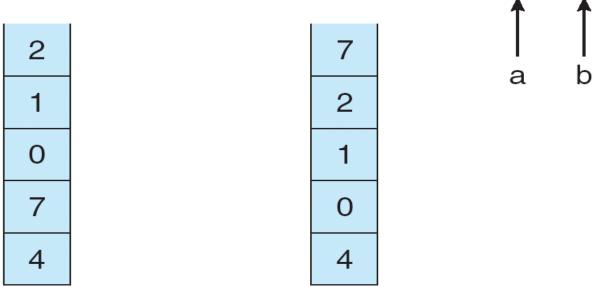

#### **Use Of A Stack to Record The Most Recent Page References**

#### reference string

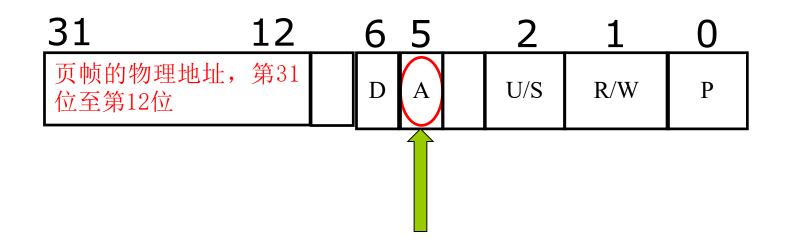

stack stack before after a b

#### **LRU Approximation Algorithms**

- Reference bit
  - With each page associate a bit, initially = 0
  - When page is referenced bit set to 1
  - Replace the one which is 0 (if one exists)
    - We do not know the order, however

#### 1. Additional-Reference-Bits Algorithm

#### ■ 附加引用位算法:

- To keep an 8-bit byte for each page in a table in memory
- At regular intervals (every 100 ms), a timer interrupt transfers control to the OS. The OS shifts the reference bit for each page into the high-order bit of its 8-bit byte, shifting the other bits right 1 bit, discarding the low-order bit. These 8-bit bytes contain the history of the page use for the last eight time periods.
- If we interpret these 8-bit bytes as unsigned integers, the page with the lowest number is the LRU page and it can be replaced.
- 被访问时左边最高位置1,定期右移并且最高位补0,于是寄存器数值最小的是最久未使用页面。

### 2. Second-Chance (clock) Algorithm

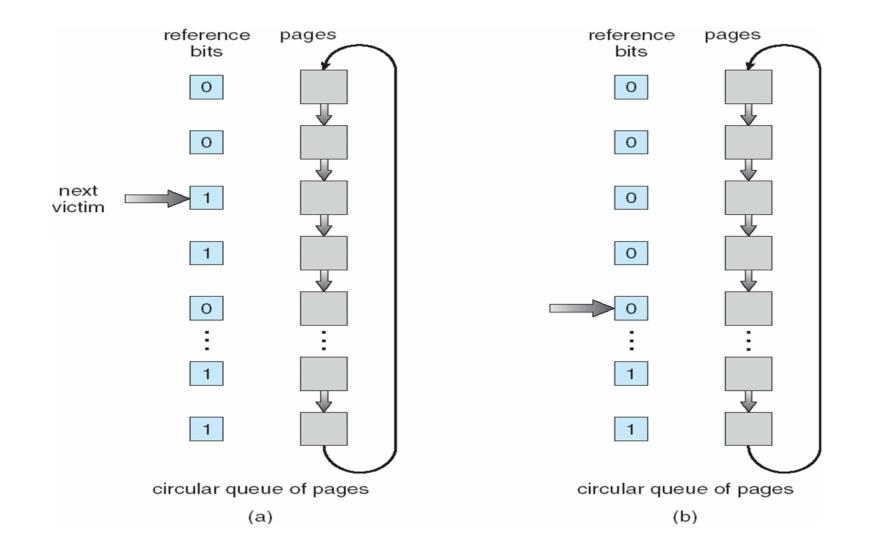

#### ■ Second chance(clock算法)

- Need reference bit
- Clock replacement
- If page to be replaced (in clock order) has reference bit = 1 then:
  - set reference bit 0
  - leave page in memory
  - replace next page (in clock order), subject to same rules

#### **Second-Chance Page-Replacement Algorithm**

#### 3. Enhanced Second-Chance Algorithm

- 增强二次机会算法(改进型的clock算法)
  - 使用引用位和修改位: 引用过或修改过置成1
  - (Reference bit, modified bit) :
    - ▶ (0,0): best page to replace
    - ▶ (0,1): not quite good for replacement
    - ▶ (1,0): will be used soon
    - ▶ (1,1): worst page to replace.
  - 淘汰次序:(0,0) ⇒(0,1)⇒(1,0)⇒(1,1)
- Macintosh系统中使用

### **Counting Algorithms**

- Keep a counter of the number of references that have been made to each page
- LFU(Least Frequently Used) Algorithm(最不经常使用算法): replaces page with smallest count
- MFU(Most Frequently Used) Algorithm(经常使用算法): based on the argument that the page with the smallest count was probably just brought in and has yet to be used

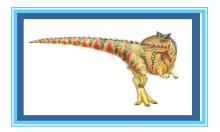

#### Page Buffering Algorithm页面缓冲算法

- 页面缓冲算法: 通过被置换页面的缓冲, 有机会找回刚被置换的页面
  - 被置换页面的选择和处理:用FIFO算法选择被置换页,把被置换的页面放入两个链表之一。即:如果页面未被修改,就将其归入到空闲页面链表的末尾,否则将其归入到已修改页面链表。
  - 需要调入新的页面时,将新页面内容读入到空闲页面链表的第一项所指的页面,然后将第一项删除。
  - 空闲页面和已修改页面,仍停留在内存中一段时间,如果这些页面被再次访问,这些页面 还在内存中。
  - 当已修改页面达到一定数目后,再将它们一起调出到外存,然后将它们归入空闲页面链表。
- VAX/VMS系统使用
- Windows、Linux页面置换算法是基于页面缓冲算法。

# 9.5 Allocation of Frames(帧分配)

### Allocation of Frames(帧分配)

- Each process needs minimum number of pages
- Example: IBM 370 6 pages to handle SS MOVE instruction:
  - instruction is 6 bytes, might span 2 pages
  - 2 pages to handle from
  - 2 pages to handle to

1条指令可能产生6次缺页

- Two major allocation schemes
  - fixed allocation
  - priority allocation

### Fixed Allocation(固定分配)

- Equal allocation (平均分配算法) For example, if there are 100 frames and 5 processes, give each process 20 frames.
- Proportional allocation (按比例分配算法) Allocate according to the size of process  $-s_i = \text{size of process } p_i$

$$-S = \sum s_i$$

- -m = total number of frames
- $-a_i =$ allocation for  $p_i = \frac{s_i}{S} \times m$

$$m = 64$$

$$s_i = 10$$

$$s_2 = 127$$

$$a_1 = \frac{10}{137} \times 64 \approx 5$$

$$a_2 = \frac{127}{137} \times 64 \approx 59$$

### Priority Allocation(优先级分配)

- Use a proportional allocation scheme using priorities rather than size
- $\blacksquare$  If process  $P_i$  generates a page fault,
  - select for replacement one of its frames
  - select for replacement a frame from a process with lower priority number

#### Global vs. Local Allocation

#### 置换策略:

- Global replacement (全局置换) process selects a replacement frame from the set of all frames; one process can take a frame from another
- Local replacement (局部置換) each process selects from only its own set of allocated frames

#### 分配策略:

- ■固定分配
- ■可变分配

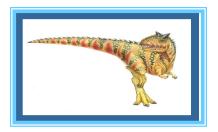

#### 帧的分配和置换策略

- ■组合成三种策略:
  - 固定分配局部置换策略
  - 可变分配全局置换策略
  - 可变分配局部置换

# 9.6 Thrashing (颠簸、抖动)

#### Thrashing (颠簸、抖动)

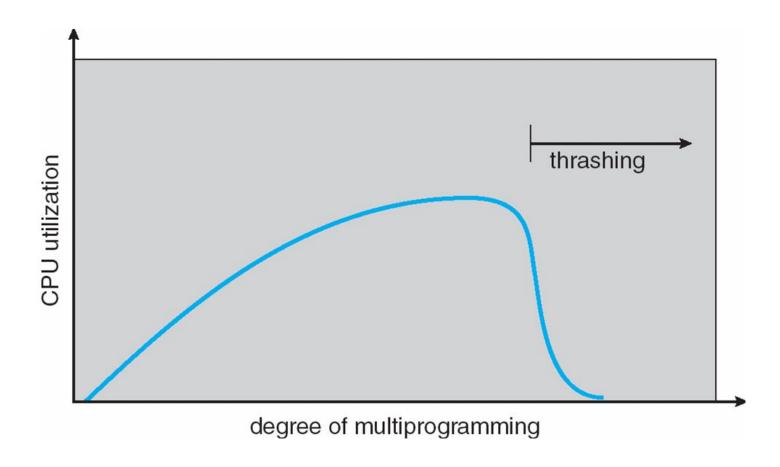

- If a process does not have "enough" pages, the page-fault rate is very high. This leads to:
  - low CPU utilization
  - operating system thinks that it needs to increase the degree of multiprogramming
  - another process added to the system
- Thrashing = a process is busy swapping pages in and out

### **Thrashing (Cont.)**

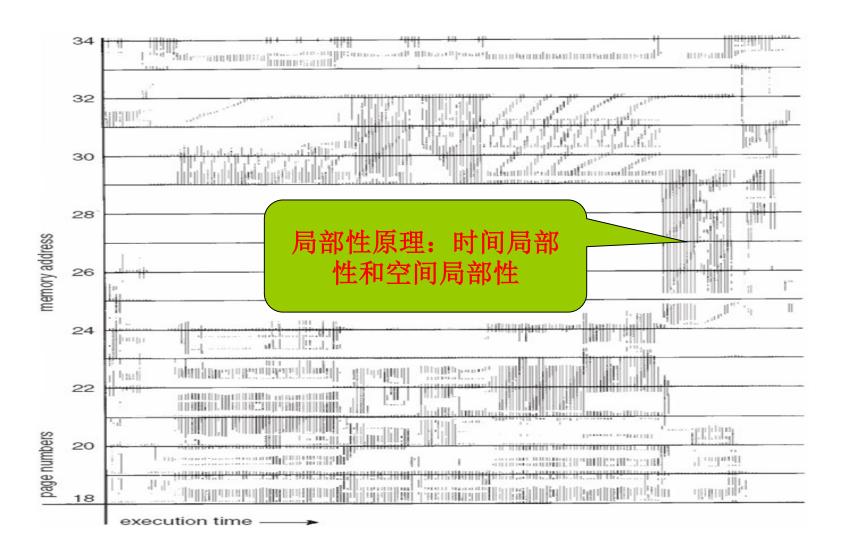

### **Demand Paging and Thrashing**

- Why does demand paging work? Locality (局部性) model
  - Process migrates from one locality to another
  - Localities may overlap
- Why does thrashing occur?
   Σ size of locality > total memory size

#### **Locality In A Memory-Reference Pattern**

### **Working-Set Model**

- working set (WS)工作集: The set of pages in the most recent  $\Delta$  page references
- $\Delta \equiv$  working-set window(工作集窗口) = a fixed number of page references Example: 10,000 instruction
- $WSS_i$  (working set size of Process  $P_i$  工作集大小) = total number of pages referenced in the most recent  $\Delta$  (varies in time)
  - if  $\Delta$  too small will not encompass entire locality.
  - if  $\Delta$  too large will encompass several localities.
  - if  $\Delta = \infty \Rightarrow$  will encompass entire program.
- $\blacksquare D = \Sigma WSS_i \equiv \text{total demand frames}; m \equiv \text{total available frames}$
- $\blacksquare$  if  $D > m \Rightarrow$  Thrashing
- Policy if D > m, then suspend one of the processes.

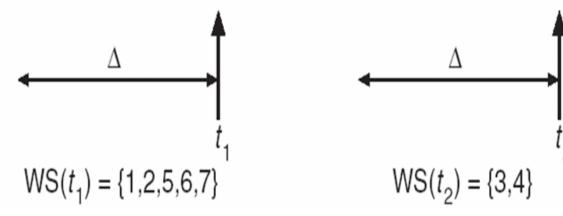

### **Working-set model**

#### page reference table

**WSS=5** 

... 261577775162341234443434441323444344...

### **Keeping Track of the Working Set**

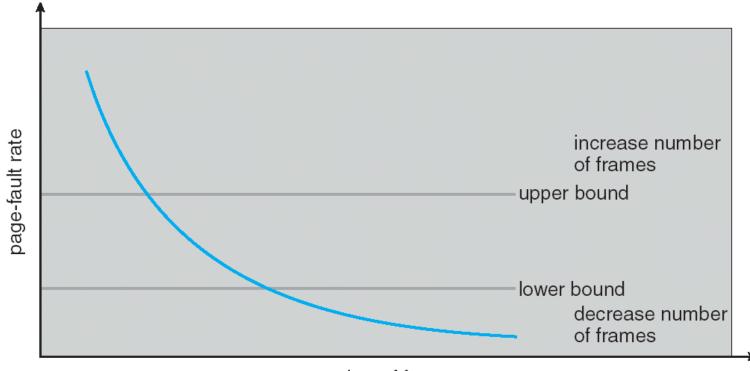

- Approximate with interval timer + a reference bit
- Example:  $\Delta = 10,000$ 
  - Timer interrupts after every 5000 time units
  - Keep in memory 2 bits for each page
  - Whenever a timer interrupts copy and sets the values of all reference bits to 0
  - If one of the bits in memory =  $1 \Rightarrow$  page in working set
- Why is this not completely accurate?
- Improvement = 10 bits and interrupt every 1000 time units

### Page-Fault Frequency Scheme (缺页频率)

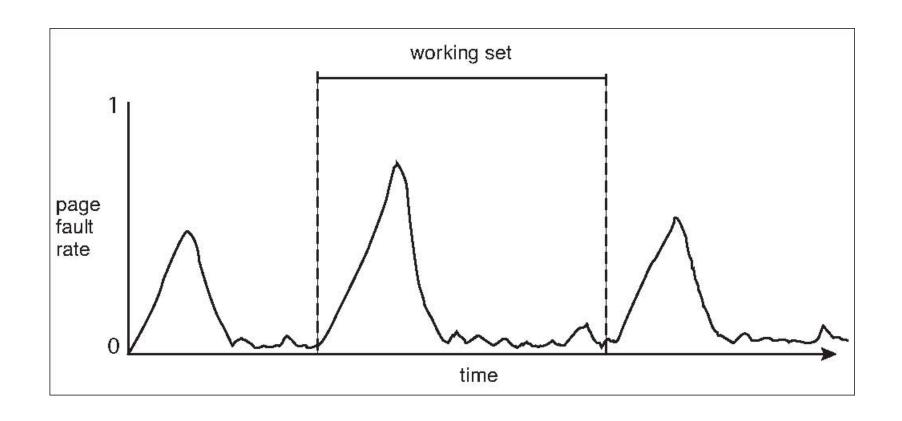

- Establish "acceptable" page-fault rate
  - If actual rate too low, process loses frame
  - If actual rate too high, process gains frame

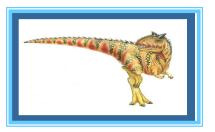

### **Working Sets and Page Fault Rates**

## 9.7 Memory-Mapped Files

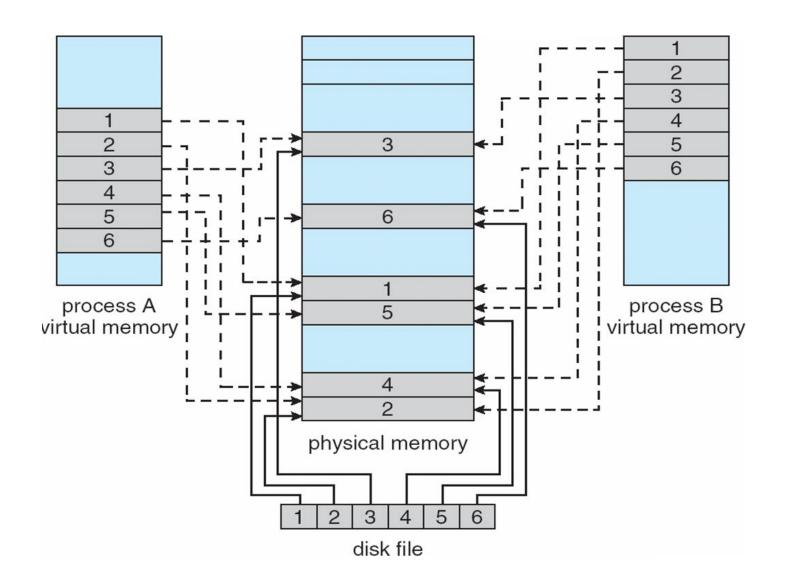

### **Memory-Mapped Files**

- Memory-mapped file I/O allows file I/O to be treated as routine memory access by mapping a disk block to a page in memory
- A file is initially read using demand paging. A page-sized portion of the file is read from the file system into a physical page. Subsequent reads/writes to/from the file are treated as ordinary memory accesses.
- Simplifies file access by treating file I/O through memory rather than read() write() system calls
- Also allows several processes to map the same file allowing the pages in memory to be shared

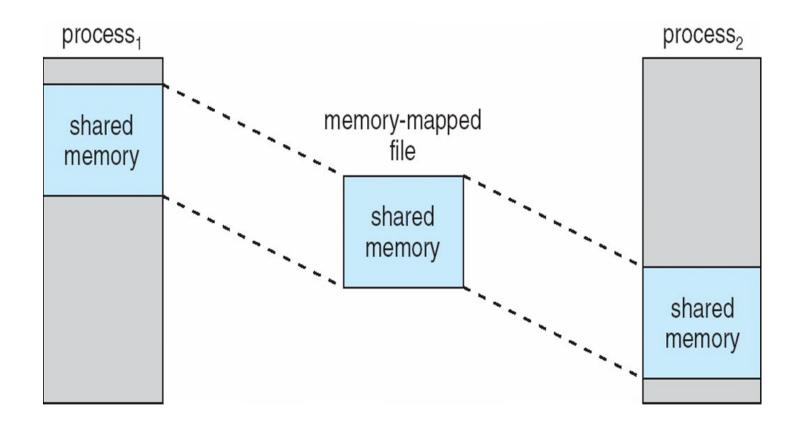

### **Memory Mapped Files**

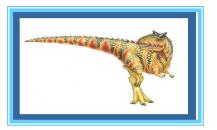

#### **Memory-Mapped Shared Memory in Windows**

# 9.8 Allocating Kernel Memory

## **Allocating Kernel Memory**

- Treated differently from user memory
- Often allocated from a free-memory pool
  - Kernel requests memory for structures of varying sizes
  - Some kernel memory needs to be contiguous

## **Buddy System**

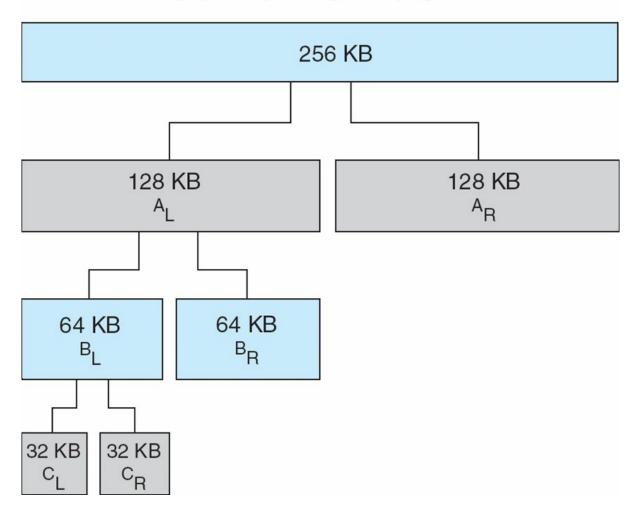

- Allocates memory from fixed-size segment consisting of physically-contiguous pages
- Memory allocated using power-of-2 allocator
  - Satisfies requests in units sized as power of 2
  - Request rounded up to next highest power of 2
  - When smaller allocation needed than is available, current chunk split into two buddies of next-lower power of 2
    - Continue until appropriate sized chunk available

# **Buddy System Allocator**

#### physically contiguous pages

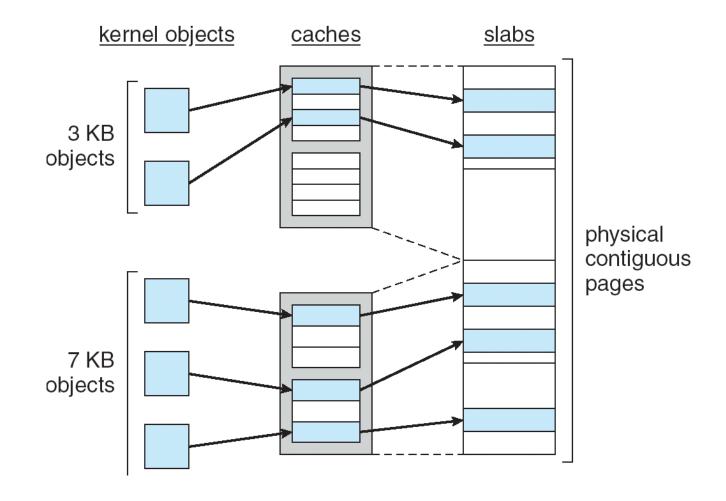

### **Slab Allocator**

- Alternate strategy
- Slab is one or more physically contiguous pages
- Cache consists of one or more slabs
- Single cache for each unique kernel data structure
  - Each cache filled with objects instantiations of the data structure
- When cache created, filled with objects marked as free
- When structures stored, objects marked as used
- If slab is full of used objects, next object allocated from empty slab
  - If no empty slabs, new slab allocated
- Benefits include no fragmentation, fast memory request satisfaction

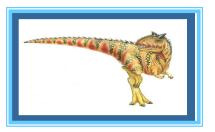

### **Slab Allocation**

# 9.9 Other Considerations

#### **Other Considerations**

- Prepaging (预调页)
- Page Size (页大小)
- TLB Reach (TLB范围)
- Program Structure (程序结构)
- I/O interlock ( I/O 锁定)

## Other Issues -- Prepaging (预调页)

#### Prepaging

- To reduce the large number of page faults that occurs at process startup
- Prepage all or some of the pages a process will need, before they are referenced
- But if prepaged pages are unused, I/O and memory was wasted
- Assume s pages are prepaged and  $\alpha$  of the pages is used
  - Is cost of  $s * \alpha$  save pages faults > or < than the cost of prepaging  $s * (1-\alpha)$  unnecessary pages?
  - $\alpha$  near zero  $\Rightarrow$  prepaging loses

## Other Issues – Page Size (页大小)

- Page size selection must take into consideration:
  - fragmentation
  - table size
  - I/O overhead
  - locality

### Other Issues - TLB Reach (TLB范围)

- TLB Reach The amount of memory accessible from the TLB
- TLB Reach = (TLB Size) X (Page Size)
- Ideally, the working set of each process is stored in the TLB
  - Otherwise there is a high degree of page faults
- Increase the Page Size
  - This may lead to an increase in fragmentation as not all applications require a large page size
- Provide Multiple Page Sizes
  - This allows applications that require larger page sizes the opportunity to use them without an increase in fragmentation

# Other Issues – Program Structure

- Program structure
  - int[128,128] data;
  - Each row is stored in one page
  - Program 1

 $128 \times 128 = 16,384$  page faults

Program 2

128 page faults

### Other Issues – I/O interlock

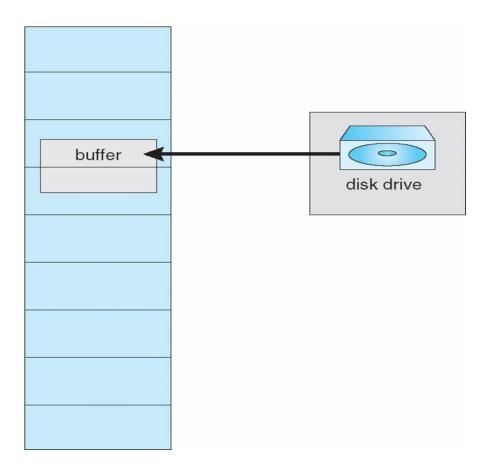

■ I/O Interlock – Pages must sometimes be locked into memory

Consider I/O - Pages that are used for copying a file from a device must be locked from being selected for eviction by a page replacement algorithm

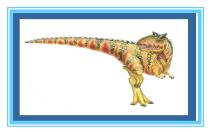

### Reason Why Frames Used For I/O Must Be In Memory

# 9.10 Operating System Examples

# **Operating System Examples**

Windows XP

Solaris

#### Windows XP

- Uses demand paging with clustering. Clustering brings in pages surrounding the faulting page
- Processes are assigned working set minimum and working set maximum
- Working set minimum is the minimum number of pages the process is guaranteed to have in memory
- A process may be assigned as many pages up to its working set maximum
- When the amount of free memory in the system falls below a threshold, automatic working set trimming is performed to restore the amount of free memory
- Working set trimming removes pages from processes that have pages in excess of their working set minimum

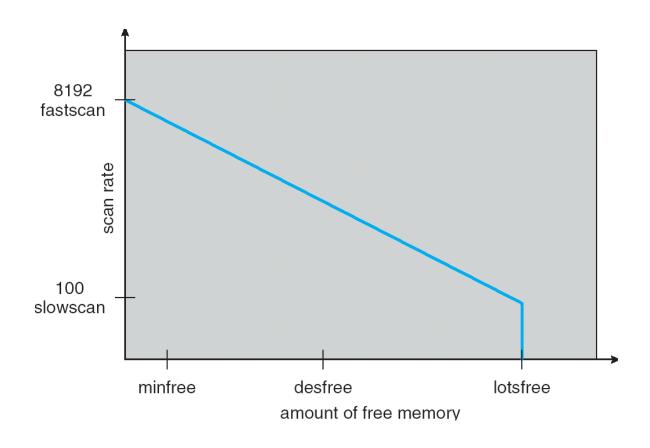

### **Solaris**

- Maintains a list of free pages to assign faulting processes
- Lotsfree threshold parameter (amount of free memory) to begin paging
- Desfree threshold parameter to increasing paging
- Minfree threshold parameter to being swapping
- Paging is performed by pageout process
- Pageout scans pages using modified clock algorithm
- Scanrate is the rate at which pages are scanned. This ranges from slowscan to fastscan
- Pageout is called more frequently depending upon the amount of free memory available

# **Solaris 2 Page Scanner**
